

Monthly mean residual, 2021-2023 — all arms shift together at the train/test boundary

- Training period is flat (Arm A slope -0.8 W/month, -13 W total over 19 months)
- All four arms drop together at January 2023 and recover partially through the year
- NO step occurs at September 2023, eight months after the shift begins
- Neither gradual degradation nor post-event damage is supported as the sole explanation by this temporal pattern.
- The January onset coincides with the train/test boundary, so part of the shift is in-sample versus held-out prediction error and the cause cannot be attributed from these outputs
