

Residual gap widens with irradiance, consistent with a proportional rather than fixed offset

The gap widens with irradiance in every arm (Arm A -465 W in the bottom deciles against -2,248 W in the top). As a fraction of predicted power, 2023 runs -12.7% to -15.1% against -1.3% to +2.0% in the training period. 2022 residuals are in-sample and 2023 are held out, so a uniform component of the gap is expected from generalisation alone — the SLOPE with irradiance is the informative part.
