

HK diagnostic five-class output versus Brazil reference distributions
clean-sensor primary population, denominator 4,745 feature-complete rows

Output is highly concentrated on Shadowing (65.71%) and Normal (30.62%). Short-Circuit and Open-Circuit are each predicted for 6 rows (0.13%). The near-absence of Short-Circuit and Open-Circuit predictions is consistent with the design conclusion that those fault-type assignments are not defensible on HK using the available aggregate sensing. Neither Brazil distribution is an expected HK prior, and HK predictions are not required to match either. HK outputs are classifier-screened diagnostic predictions, not validated physical fault assignments.
