

Screening behaviour is stable across source folds

The concentration is not attributable to a single unstable fold model: unanimous binary agreement 87.84%, pairwise 92.16-95.43%. The uncalibrated ensemble anomalous score is used for ranking and shape only; it is not an estimated probability that the HK system is faulty, and the binary flag derives solely from the five-class argmax. No cut-off is drawn on it.

HK outputs are classifier-screened diagnostic predictions, not validated physical fault assignments.
